125. Valid Palindrome

Easy | Topics | Companies

A phrase is a **palindrome** if, after converting all uppercase letters into lowercase letters and removing all non-alphanumeric characters, it reads the same forward and backward. Alphanumeric characters include letters and numbers.

Given a string `s`, return `true` *if it is a* ***palindrome****, or* `false` *otherwise*.

Example 1:

```
Input: s = "A man, a plan, a canal: Panama"
Output: true
Explanation: "amanaplanacanalpanama" is a palindrome.
```

Example 2:

```
Input: s = "race a car"
Output: false
Explanation: "raceacar" is not a palindrome.
```

Example 3:

```
Input: s = " "
Output: true
Explanation: s is an empty string "" after removing non-alphanumeric characters.
Since an empty string reads the same forward and backward, it is a palindrome.
```

Constraints:

- `1 <= s.length <= 2 * 10^5`
- `s` consists only of printable ASCII characters.

811. Subdomain Visit Count

Medium | Topics | Companies

A website domain `"discuss.leetcode.com"` consists of various subdomains. At the top level, we have `"com"`, at the next level, we have `"leetcode.com"` and at the lowest level, `"discuss.leetcode.com"`. When we visit a domain like `"discuss.leetcode.com"`, we will also visit the parent domains `"leetcode.com"` and `"com"` implicitly.

A **count-paired domain** is a domain that has one of the two formats `"rep d1.d2.d3"` or `"rep d1.d2"` where `rep` is the number of visits to the domain and `d1.d2.d3` is the domain itself.

- For example, `"9001 discuss.leetcode.com"` is a **count-paired domain** that indicates that `discuss.leetcode.com` was visited `9001` times.

Given an array of **count-paired domains** `cpdomains`, return *an array of the **count-paired domains** of each subdomain in the input*. You may return the answer in **any order**.

Example 1:

```
Input: cpdomains = ["9001 discuss.leetcode.com"]
Output: ["9001 leetcode.com","9001 discuss.leetcode.com","9001 com"]
Explanation: We only have one website domain: "discuss.leetcode.com".
As discussed above, the subdomain "leetcode.com" and "com" will also be visited. So they will all be visited 9001 times.
```

Example 2:

```
Input: cpdomains = ["900 google.mail.com", "50 yahoo.com", "1 intel.mail.com", "5 wiki.org"]
Output: ["901 mail.com","50 yahoo.com","900 google.mail.com","5 wiki.org","5 org","1 intel.mail.com","951 com"]
Explanation: We will visit "google.mail.com" 900 times, "yahoo.com" 50 times, "intel.mail.com" once and "wiki.org" 5 times.
For the subdomains, we will visit "mail.com" 900 + 1 = 901 times, "com" 900 + 50 + 1 = 951 times, and "org" 5 times.
```

Code

Python • Auto

```python
# collections is a built-in Python module that provides specialized container datatypes like
Counter, defaultdict, deque, etc.
class Solution(object):
    def subdomainVisits(self, cpdomains):
        # ans will store counts for each subdomain
        ans = collections.Counter()

        # Loop through each domain in the input list
        for domain in cpdomains:
            # Split the string into count and domain name
            count, domain = domain.split()
            count = int(count)  # convert count to integer

            # Split the domain into parts (e.g., "discuss.leetcode.com" → ["discuss",
"leetcode", "com"])
            frags = domain.split('.')

            # Iterate over all possible subdomains
            for i in range(len(frags)):
                # join the subdomain parts from i to end
                # For i=0 → "discuss.leetcode.com"
                # For i=1 → "leetcode.com"
                # For i=2 → "com"
                ans[".".join(frags[i:])] += count  # Add count to each subdomain

        # Format the result as a list of "count domain" strings
        formatted_list = []
        for dom, ct in ans.items():
            formatted_string = "{} {}".format(ct, dom)
            formatted_list.append(formatted_string)

        return formatted_list
```

Col 24

`Counter` acts like a normal dictionary, but:

- You **don't need to check** if a key exists before adding to it.
- Missing keys **start with a default count of 0**, so you can safely do `c[key] += 1`

1. Two Sum

Solved

Easy | Topics | Companies | Hint

Given an array of integers `nums` and an integer `target`, return *indices of the two numbers such that they add up to* `target`.

You may assume that each input would have ***exactly* one solution**, and you may not use the *same* element twice.

You can return the answer in any order.

Example 1:

```
Input: nums = [2,7,11,15], target = 9
Output: [0,1]
Explanation: Because nums[0] + nums[1] == 9, we return [0, 1].
```

Example 2:

```
Input: nums = [3,2,4], target = 6
Output: [1,2]
```

Example 3:

```
Input: nums = [3,3], target = 6
Output: [0,1]
```

Constraints:

- `2 <= nums.length <= 10^4`
- `-10^9 <= nums[i] <= 10^9`
- `-10^9 <= target <= 10^9`

3. Longest Substring Without Repeating Characters

Solved

Medium | Topics | Companies | Hint

Given a string `s`, find the length of the **longest** **substring** without repeating characters.

Example 1:

```
Input: s = "abcabcbb"
Output: 3
Explanation: The answer is "abc", with the length of 3.
```

Example 2:

```
Input: s = "bbbbb"
Output: 1
Explanation: The answer is "b", with the length of 1.
```

Example 3:

```
Input: s = "pwwkew"
Output: 3
Explanation: The answer is "wke", with the length of 3.
Notice that the answer must be a substring, "pwke" is a subsequence and not a substring.
```

Constraints:

- `0 <= s.length <= 5 * 10^4`
- `s` consists of English letters, digits, symbols and spaces.

966. Vowel Spellchecker

Solved

Medium | Topics | Companies

Given a `wordlist`, we want to implement a spellchecker that converts a query word into a correct word.

For a given `query` word, the spell checker handles two categories of spelling mistakes:

- Capitalization: If the query matches a word in the wordlist (**case-insensitive**), then the query word is returned with the same case as the case in the wordlist.
  - Example: `wordlist = ["yellow"]`, `query = "YellOw"`: `correct = "yellow"`
  - Example: `wordlist = ["Yellow"]`, `query = "yellow"`: `correct = "Yellow"`
  - Example: `wordlist = ["yellow"]`, `query = "yellow"`: `correct = "yellow"`
- Vowel Errors: If after replacing the vowels `('a', 'e', 'i', 'o', 'u')` of the query word with any vowel individually, it matches a word in the wordlist (**case-insensitive**), then the query word is returned with the same case as the match in the wordlist.
  - Example: `wordlist = ["YellOw"]`, `query = "yollow"`: `correct = "YellOw"`
  - Example: `wordlist = ["YellOw"]`, `query = "yeellow"`: `correct = ""` (no match)
  - Example: `wordlist = ["YellOw"]`, `query = "yllw"`: `correct = ""` (no match)

In addition, the spell checker operates under the following precedence rules:

- When the query exactly matches a word in the wordlist (**case-sensitive**), you should return the same word back.
- When the query matches a word up to capitlization, you should return the first such match in the wordlist.
- When the query matches a word up to vowel errors, you should return the first such match in the wordlist.
- If the query has no matches in the wordlist, you should return the empty string.

Given some `queries`, return a list of words `answer`, where `answer[i]` is the correct word for `query = queries[i]`.

Code

Python3 | Auto

```
1
```

Example 1:

```
Input: wordlist = ["KiTe","kite","hare","Hare"], queries =
["kite","Kite","KiTe","Hare","HARE","Hear","hear","keti","keet","keto"]
Output: ["kite","KiTe","KiTe","Hare","hare","","","KiTe","","KiTe"]
```

Example 2:

```
Input: wordlist = ["yellow"], queries = ["YellOw"]
Output: ["yellow"]
```

966. Vowel Spellchecker

Solved

Medium | Topics | Companies

Given a `wordlist`, we want to implement a spellchecker that converts a query word into a correct word.

For a given `query` word, the spell checker handles two categories of spelling mistakes:

- Capitalization: If the query matches a word in the wordlist (**case-insensitive**), then the query word is returned with the same case as the case in the wordlist.
  - Example: `wordlist = ["yellow"]`, `query = "YellOw"`: `correct = "yellow"`
  - Example: `wordlist = ["Yellow"]`, `query = "yellow"`: `correct = "Yellow"`
  - Example: `wordlist = ["yellow"]`, `query = "yellow"`: `correct = "yellow"`
- Vowel Errors: If after replacing the vowels `('a', 'e', 'i', 'o', 'u')` of the query word with any vowel individually, it matches a word in the wordlist (**case-insensitive**), then the query word is returned with the same case as the match in the wordlist.
  - Example: `wordlist = ["YellOw"]`, `query = "yollow"`: `correct = "YellOw"`
  - Example: `wordlist = ["YellOw"]`, `query = "yeellow"`: `correct = ""` (no match)
  - Example: `wordlist = ["YellOw"]`, `query = "yllw"`: `correct = ""` (no match)

In addition, the spell checker operates under the following precedence rules:

- When the query exactly matches a word in the wordlist (**case-sensitive**), you should return the same word back.
- When the query matches a word up to capitlization, you should return the first such match in the wordlist.
- When the query matches a word up to vowel errors, you should return the first such match in the wordlist.
- If the query has no matches in the wordlist, you should return the empty string.

Given some `queries`, return a list of words `answer`, where `answer[i]` is the correct word for `query = queries[i]`.

Code

Python3 | Auto

```python
class Solution(object):
    def spellchecker(self, wordlist, queries):
        words_perfect = set(wordlist)
        words_cap = {}
        words_vow = {}

        def devowel(word):
            return "".join('*' if c in 'aeiou' else c
                for c in word)

        for word in wordlist:
            wordlow = word.lower()
            words_cap.setdefault(wordlow, word)
            words_vow.setdefault(devowel(wordlow), word)

        def solve(query):
            if query in words_perfect:
                return query

            queryL = query.lower()
            if queryL in words_cap:
                return words_cap[queryL]

            queryLV = devowel(queryL)
            if queryLV in words_vow:
                return words_vow[queryLV]
            return ""

        results = []
        for query in queries:
            result = solve(query)
            results.append(result)
        return results
```
